During the course of commercial construction, it is necessary to fit walls and floors with junction boxes or other supporting members prior to covering the walls and floors with wallboard or other paneling. Typically, the junction boxes are attached to the walls and/or the subfloor in such a manner that they are not visible once the wallboard or the subflooring is installed. Ordinarily, the junction boxes are attached to the subfloor by drilling holes in the subfloor and securing the junction boxes to the subfloor by anchoring them within the holes. Because this type of attachment is unsightly, it is common to attach the junction boxes to the walls and/or the subfloor with thin strips of drywall screws. This leaves no impression in the drywall and, therefore, leaves the junction boxes invisible once the wallboard or subflooring is installed. Although fasteners of this type are effective in securing the junction boxes to the subfloor, they are subject to one drawback: when the junction boxes are mounted to the subfloor and the wall board is mounted to the junction boxes, the wall board tends to pull the junction boxes out of the holes in the subfloor. In an effort to eliminate this problem, builders sometimes secure the junction boxes to the subfloor with special screws. Alternatively, builders use mounting plates that are nailed or screwed to the subfloor and then to the junction boxes. However, these efforts are sometimes inadequate and result in a junction box that is insecure and which is not in a secure position to receive other fasteners. The present invention is directed to overcoming one or more of the problems discussed above in a novel and simple manner.

Optical structures that include three-dimensional sub-wavelength features on a two-dimensional surface are known. For example, optically resolvable features, such as sub-wavelength gratings, may be formed by

a photolithographic patterning of a thin film material. It is also known that light can be focused by a three-dimensional structure, to the focal point, at a distance. While each of these structures has its own particular advantages and disadvantages, each has the disadvantage of a need for making a particular feature pattern to be used with the particular optical structure. Such features are made by developing, for example, a photograph of the three-dimensional structure to be formed on a surface, or using
